Abstract of the thesis presented to the Senate of Universiti Putra Malaysia in fulfillment of the requirements for the degree of Master of Science

**MICROSTRUCTURE AND DYNAMIC MAGNETIC PROPERTIES OF
THALLIUM-BASED SUPERCONDUCTORS**

By

ABDUL TALIB BIN SHAARI

July 2002

Chairman: Professor Dr. Abdul Halim Shaari
Faculty: Science and Environmental Studies

Ac susceptibility study is one of the best methods in characterizing bulk superconductors. Four systems (A, B, C and D) of Thallium-based bulk superconductors were analyzed using this method. They were $A = (\text{Tl}_{0.85}\text{Cr}_{0.15}) \text{Sr}_2 (\text{Ca}_{1-x}\text{Pr}_x) \text{Cu}_2\text{O}_7$, $B = (\text{Tl}_{0.85}\text{Cr}_{0.15}) \text{Sr}_2 (\text{Ca}_{1-x}\text{Nd}_x) \text{Cu}_2\text{O}_7$, $C = (\text{Tl}_{0.85}\text{Cr}_{0.15}) \text{Sr}_2 (\text{Ca}_{1-x}\text{Pr}_x) \text{Cu}_2\text{O}_7$, and $D = (\text{Tl}_{0.85}\text{Cr}_{0.15}) \text{Sr}_2 (\text{Sr}_{1-x}\text{Pr}_x) \text{Cu}_2\text{O}_7$. The temperature dependent ac susceptibility curves and field dependent ac susceptibility curves were obtained using Lake Shore AC Susceptometer Model 7000. The dimensions of each sample were 2mmx2mmx10mm. Certain ranges of temperatures were identified from temperature dependent ac susceptibility curves for use in plotting the field dependent ac susceptibility curves for each sample. The applied fields (0.1 – 10 Oersted) were not high enough to observe the contributions from intragranular supercurrents. Therefore the data obtained were from the intergranular matrix. Bean's Model is used to explain the dynamic magnetic properties that resulted from the data T_c , T_p and T_{c_j} that were obtained from temperature dependent ac susceptibility curves. I_0 was calculated from T_c and T_{c_j} using the Ambegaokar-Baratoff formula and $J_c(T)$ were

calculated from Bean's model. T_c and I_0 were plotted against the concentration x and $J_c(T)$ were plotted against temperature T .

From this research work the effect of doping in general reduced the T_c and I_0 values. For system D, the values fall gradually where as for the rest they fall very fast especially those of system B. These are reflected in the graphs of T_c versus x and I_0 versus x . The degree of compactness can be drawn as follows: $D > C > A > B$.

From $J_c(T)$ versus T , $J_c(T)$ values drop gradually for system D whereas for the other systems, $J_c(T)$ values drop very fast. All the $J_c(T)$ maximum values were increased as the field increased and these were attained at lower temperatures. At particular field, as the concentration increased, these were attained at lower temperatures also.

Kim's Model was used to explain the data obtained from field dependent ac susceptibility curves. It was found that systems D and C have certain range of temperatures where the curves follow Kim's Model. For example, these are reflected in the curves $\chi_m''(H_m)$ versus $-\chi_m'(H_m)$ and $\chi_m''(H_m)$ versus $\log H_m$ at various temperatures and dopings for system D, $x = 0.3$, $T = 59$ K, $J_c(H) = 2.66 \times 10^5 \text{ Am}^{-2}$, for system C, $x = 0.2$, $T = 70$ K, $J_c(H) = 1.66 \times 10^5 \text{ Am}^{-2}$ and for system A, $x = 0.2$, $T = 53$ K, $J_c(H) = 3.46 \times 10^5 \text{ Am}^{-2}$.

SEM photographs were also taken and analyzed. The microstructures of systems A and B are more flat and round in shape. They look porous and having bigger voids whereas those of systems D and C have long rectangular shape or rod-

liked in shape and look more compact and homogenous. The compactness and small voids probably lead to slow reduction of I_0 and T_c in systems D and C. Thus systems D and C are better connected than those of Systems A and B.

Thus the doping and heat treatment have certain effects on the dynamic magnetic properties of these superconductors as shown in the values of the critical current density J_c (T), J_c (H), I_0 and T_c . Further heating (1.5 hours), as in system A, did not strengthen the weak-links.

From the analysis of data obtained from temperature dependent ac susceptibility curves, analysis of the field dependent ac susceptibility curves and the analysis of the SEM photographs, system D, $x = 0.3$ is believed to have the best microstructure that give the dynamic magnetic properties which can be explained by the Bean's Model and Kim's Model.

Abstrak tesis yang dikemukakan kepada Senat Universiti Putra Malaysia bagi memenuhi keperluan ijazah Master Sains

**PENYELIDIKAN MIKROSTRUKTUR DAN CIRI-CIRI DINAMIK
KEMAGNETAN BAGI BAHAN SUPERKONDUCTOR
BERASASKAN THALLIUM**

Oleh

ABDUL TALIB BIN SHAARI

Fakulti: Sains dan Pengajian Alam Sekitar

Penyelidikan kerentanan au adalah salah satu cara yang terbaik untuk mengkaji ciri-ciri kemagnetan bahan superkonduktor. Empat sistem superkonduktor berasaskan Thallium (Sistem A, B, C and D) telah dikaji menggunakan teknik ini. Empat system itu ialah sebagai berikut: $A = (Tl_{0.85}Cr_{0.15}) Sr_2 (Ca_{1-x}Pr_x) Cu_2O_7$, $B = (Tl_{0.85}Cr_{0.15}) Sr_2 (Ca_{1-x}Nd_x) Cu_2O_7$, $C = (Tl_{0.85}Cr_{0.15}) Sr_2 Ca_{1-x}Pr_x Cu_2O_7$, $D = (Tl_{0.85}Cr_{0.15}) Sr_2 (Sr_{1-x}Pr_x) Cu_2O_7$. Graf kerentanan au yang bergantung kepada suhu dan bergantung pada medan didapati menggunakan alat A.C. Susceptometer Model 7000. Julat suhu dipilih dari graf kerentanan au bergantung kepada suhu untuk digunakan melakar graf kerentanan au bergantung kepada medan. Dimensi sampel ialah 2mm x 2mm x 10mm. Mikrostruktur tiap sampel diambil dengan menggunakan alat SEM. Daripada graf kerentanan au bergantung pada medan, julat suhu yang mengikuti tuntutan model keadaan genting (Kim's Model) telah dipilih. Data yang akan didapati adalah dari matriks antaragranular. Model Bean digunakan untuk menganalisis data dari graf

kerentanan au bergantung pada suhu. I_0 dihasilkan dengan menggunakan formula Ambegaokar-Baratoff dengan menggunakan T_c dan T_{cJ} yang didapati dari graf kerentanan au bergantung kepada suhu dan $J_c(T)$ dikira dari Model Bean. Suhu T_c dan I_0 diplotkan melawan x dan $J_c(T)$ diplotkan melawan suhu T .

Daripada penyelidikan ini akibat daripada pendopan, T_c dan I_0 telah menurun nilainya. Bagi sampel D nilai ini menurun dengan perlahan tetapi bagi sistem yang lain nilai ini menurun dengan cepat. Ini menunjukkan bahawa sistem D mempunyai mikrostruktur yang padat dari yang lain. Kepadatan itu boleh ditulis sebagai berikut: $D > C > A > B$.

Daripada Graf $J_c(T)$ melawan T , $J_c(T)$ menurun secara perlahan juga bagi sistem D. Sistem lain menurun dengan cepat terutama sistem B. Semua nilai maxima $J_c(T)$ meningkat bila medan bertambah tetapi pada suhu rendah. Pada nilai medan tertentu, nilai $J_c(T)$ bertambah bila x bertambah tetapi pada suhu rendah juga.

Model Kim digunakan untuk menganalisis data daripada graf bergantung pada medan. Juga didapati bahawa sistem D dan C mempunyai julat suhu lebih besar yang memenuhi tuntutan Model Kim. Ini boleh dilihat pada graf $\chi_m''(H_m)$ melawan $-\chi_m'$ (H_m) dan graf $\chi_m''(H_m)$ melawan $\log H_m$ untuk sistem D, $x = 0.3$, $T = 59$ K, $J_c(H) = 2.66 \times 10^5 \text{ Am}^{-2}$, untuk sistem C, $x = 0.2$, $T = 70$ K, $J_c(H) = 1.66 \times 10^5 \text{ Am}^{-2}$ dan sistem A, $x = 0.2$, $T = 53$ K, $J_c(H) = 3.46 \times 10^5 \text{ Am}^{-2}$.

Gambar SEM juga diambil bagi semua sampel dan dianalisis. Didapati mikrostruktur bagi sistem A dan B bulat, besar dan leper, tetapi bagi sistem

D dan C condong kepada bentuk segiempat panjang dan kecil. Mikrostruktur sistem D dan C nampak lebih padat daripada sistem A dan B. Mungkin kepadatan ini menyebabkan nilai T_c dan nilai I_0 menurun lebih lambat berbanding dengan sistem A dan B.

Nampaknya pendopan ada kesan kepada nilai $J_c(T)$, $J_c(H)$, I_0 dan T_c tetapi pemanasan lebih (1.5 jam) tidak memberi kesan kepada nilai nilai ini terutama pada nilai I_0 .

Daripada analisis data daripada kerentanan au bergantung pada suhu dan yang bergantung pada medan dan analisis mikrostruktur dari gambar SEM, dibuat kesimpulan bahawa sistem D, $x = 0.3$ adalah sistem yang mempunyai mikrostruktur yang terbaik yang mempunyai ciri ciri kemagnetan dinamik yang boleh diterangkan dengan menggunakan Model Bean dan Model Kim.

ACKNOWLEDGEMENTS

First and foremost, I would like to acknowledge my supervisor, Professor Dr. Abdul Halim Shaari , for giving me the opportunity to pursue my master's degree under his supervision and also to Associate Professor Dr. Wan Mahmood Mat Yunus and Associate Professor Dr. Jamil Suradi from Physics Department, Faculty of Science and Environmental Studies, UPM as members of the Examination Committee. Special thanks to Professor Dr. Roslan Abdul Shukor from UKM for providing the thallium-based superconductor samples for my ac susceptibility and SEM studies and to Dr. S.B.Mohamed who is now at Tsukuba University, Tokyo, Japan and Dr. Azhan Hashim, who is now at UiTM, Jengka, Pahang for their valueable discussions and helps during my course of experiments Also I would like to thank En. Lim Kean Pah, Kabashi, A.I.Malik, Koh Soog Foo, Yu Ong Sing, Abdul Halim Baijan, Abdullah Cik, Imad, Pn. Iftetan, Ari , Huda Abdullah, Teh Jio Yew and Cik Sharmiwati Mohd. Shariff for their helps in using the computers and other instruments in the laboratory.

Particular thanks are also owed to En.Razak Harun for his help in the usage of instruments in the laboratory and to Cik Suleka Madhavan, Cik Azilah Abdul Jalil and Encik Ho Oi Kuan, for their helps in preparing the samples and the use of SEM instruments and to Encik Baharuddin Ibrahim and Encik Zulambiar Bahari from Multimedia Laboratory for helping me in using the Scanner.

I certify that an Examination Committee met on the 5th July 2002 to conduct the final examination of Abdul Talib bin Shaari on his Master of Science thesis entitled "Microstructure and Dynamic Magnetic Properties of Thallium-based Superconductors" in accordance with Universiti Pertanian Malaysia (Higher Degree) Act 1980 and Universiti Pertanian Malaysia (Higher Degree) Regulations 1981. The Committee recommends that the candidate be awarded the relevant degree. Members of the Examination Committee are as follows:

HJ. MOHD. MAAROF MOKSIN, Ph.D.

Associate Professor
Faculty of Science and Environmental Studies,
Universiti Putra Malaysia
(Chairman)

ABDUL HALIM SHAARI, Ph.D.

Professor
Faculty of Science and Environmental Studies
Universiti Putra Malaysia
(Member)

WAN MAHMOOD MAT YUNUS, Ph.D.

CHAPTER I

GENERAL INTRODUCTION.

What is a superconductor? It is a material which exhibits two distinct properties, that is, zero resistivity: $\rho = 0$ for all $T < T_c$ and zero magnetic induction: $B = 0$ inside the superconductor. The magnetic inductance becomes zero inside the superconductor when it is cooled below T_c in a weak external magnetic field. The magnetic flux is expelled from the interior of the superconductor. This effect is called the Meissner-Ochsenfeld effect after its discoverers.

In 1957, Alexei Abrikosov studied the behaviour of superconductors in an external magnetic field and found that there are two types of superconductors: Type-I and Type-II superconductors. Type-I expelled magnetic flux completely from their interior while Type-II do it completely only at small fields but partially at higher fields. Thanks to this property, i.e., the formation of the so-called mixed state, this Type-II can sustain superconductivity even in fields higher than 10 Tesla. Because of this, Type-II superconductors are of interest for most large-scale application.

In zero field cooled (ZFC) condition (See Figure 1.1), the superconductor is cooled first below T_c and when the field is applied below T_c , the field is excluded. This is called **magnetic shielding**. But in field cooled (FC) condition (See Figure 1.1) when constant field is applied before it is cooled below T_c and when it is cooled

below T_c , while the field is kept constant, the field is expelled and this called the **Meissner effect**.

Figure 1.1: Effect of zero field cooling (ZFC) and field cooling (FC) On a superconductor.
(Source: Superconductivity; Charles P. Poole, Jr, Academic Press, 1995)

High T_c Superconductors

High T_c superconductors belong to Type-II superconductors. Examples of high T_c superconductors are YBCO, BSCCO, TBCCO and finally HBCCO systems. The highest T_c for YBCO system belongs to YBCO (123) phase, that is, $T_c = 92$ K, while for BSCCO (2223), $T_c = 110$ K, and lastly for TBCCO (2223) and HBCCO (1223) $T_c = 125$ K and $T_c = 153$ K respectively. These High T_c superconductors are usually granular and since it is granular the problems of weak-links occur.

Thallium-Based High T_c Superconductors

Thallium-based system (Figure 1.2 and Table 1.1) was discovered by Z.Z.Sheng and A.M.Hermann (1988). $TlBaCuO$ has $T_c = 81$ K and it rose to 100 K when Ca was included in the system and in 1993, $Tl-2223$ was discovered with the highest $T_c = 125$ K (Table 1.1). Thallium-based systems are considered today as the most likely candidates for power applications such as transmission lines and various magnetic systems since they have low flux creep. The thallium single layer materials such as $Tl-1223$ show less flux creep than the more anisotropic double layer such as $Bi-2212$, $Bi-2223$ and $Tl-2223$. The insulator thickness, the spacing between the copper oxide layer blocks is an important parameter for flux creep. Among the materials of the Tl -based group the best position of the irreversibility line belongs to this $Tl-1223$ phase. It is accepted that stronger coupling between conducting $Cu-O$ planes separated by single-layer insulating $Tl-O$ plane is responsible for the improved properties of this kind of material in higher magnetic fields. These types of applications requires J_c values in the range of 10^4 - 10^5 A cm^{-2} which are
